

Enable Hyper-V in Windows, Configure Storage, Network and Configure Virtual Machines-20

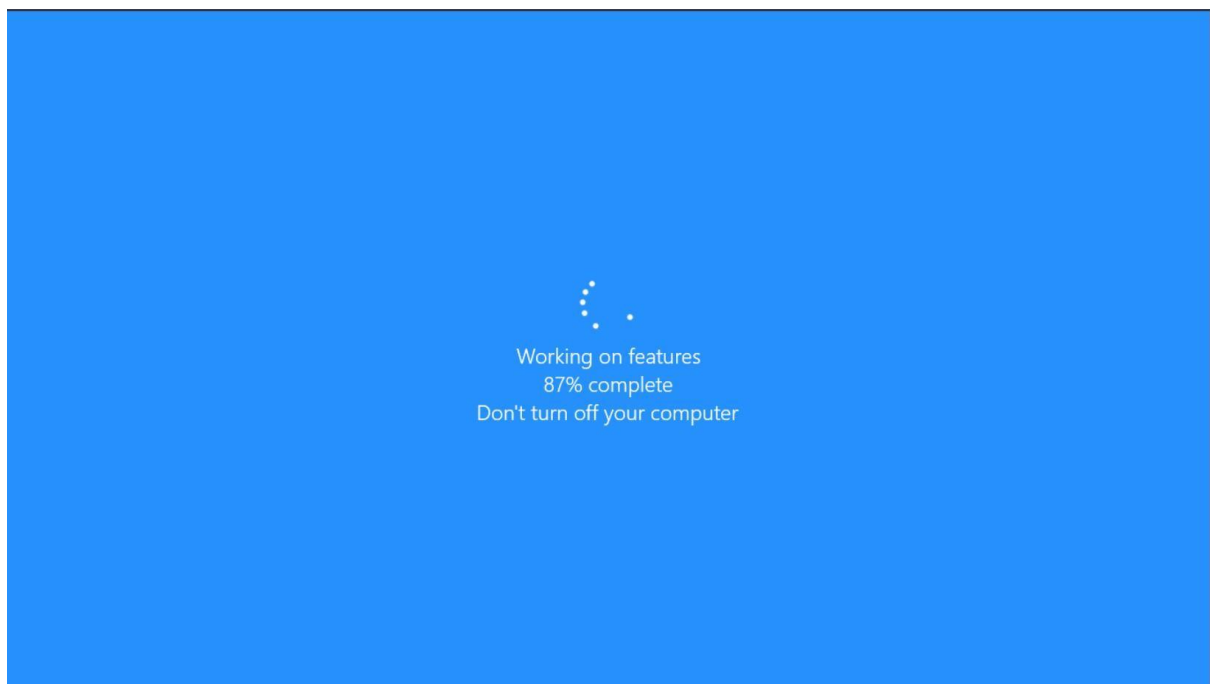

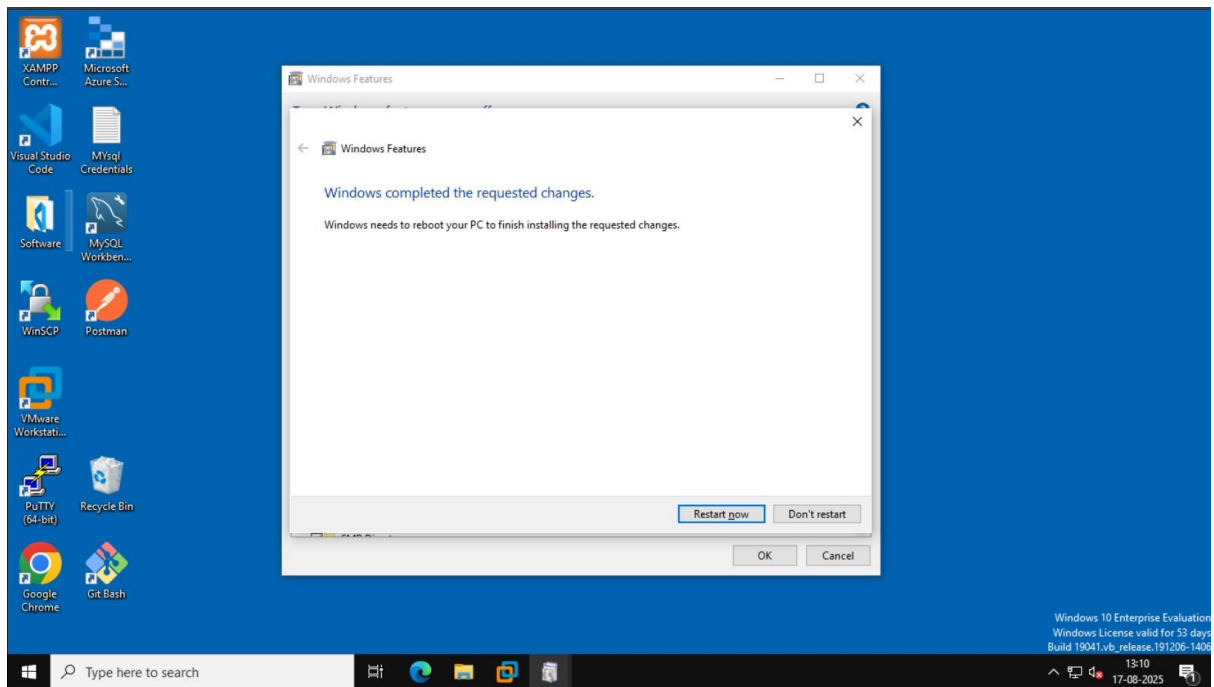

Hyper-V is a Windows feature that lets you create and run virtual machines on your system. It provides hardware-level virtualization, allowing multiple operating systems to run on a single physical machine with isolation. With Hyper-V, you can test applications, set up development or lab environments, and run older OS versions without affecting the host. It also supports features like dynamic memory, live migration, and checkpoints, making it useful for both personal and enterprise use. First we need to enable the hyper-v in windows features on or off

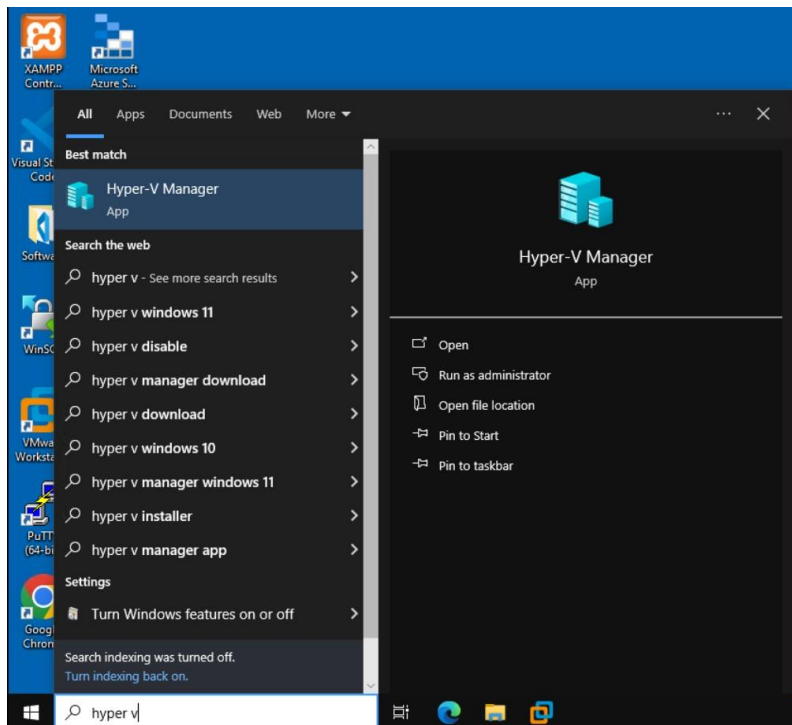

By ticking the hyper-v and click ok

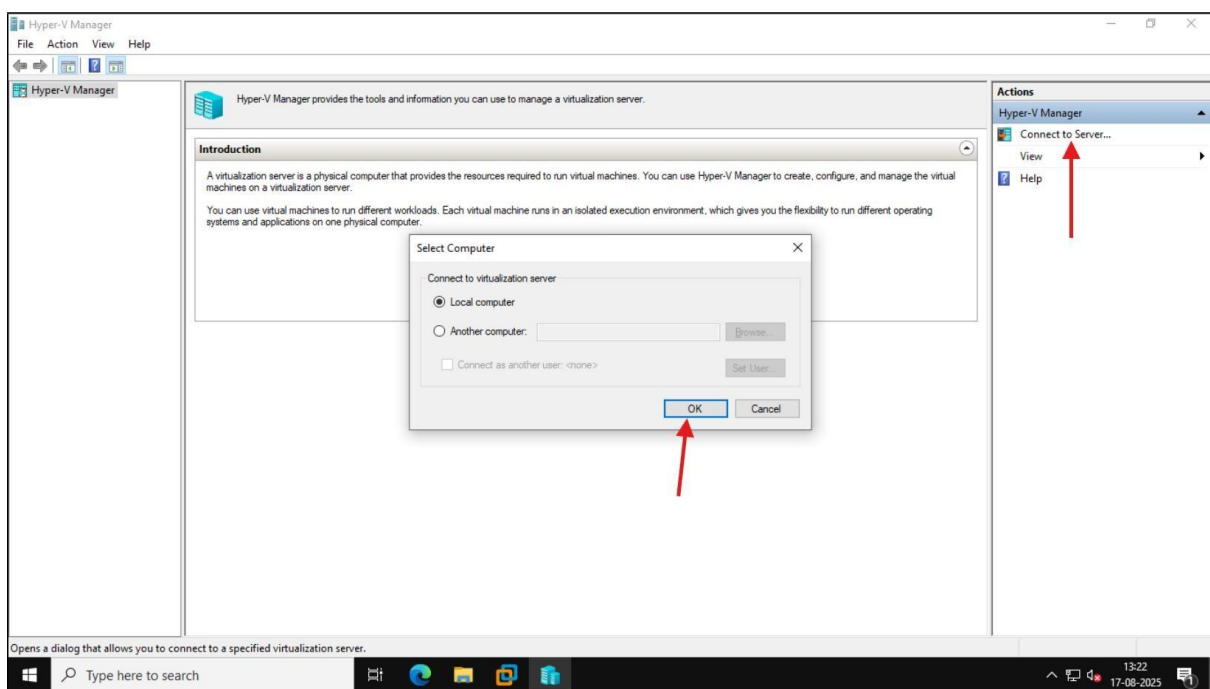

It will ask for a restart the computer and wait for it to update and let it complete

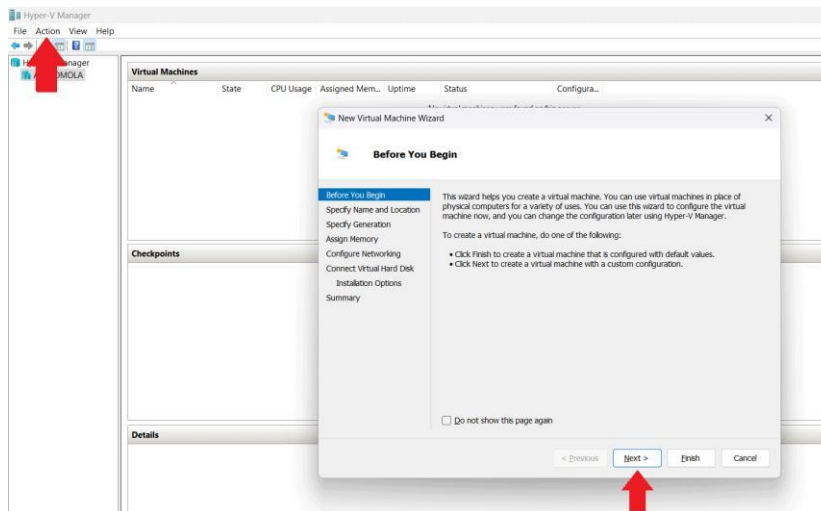

After restart we can now search for Hyper-v Manager open it

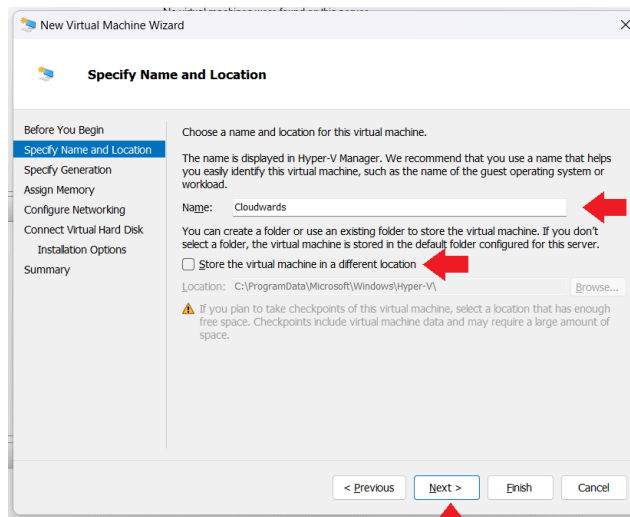

Connect to server click ok

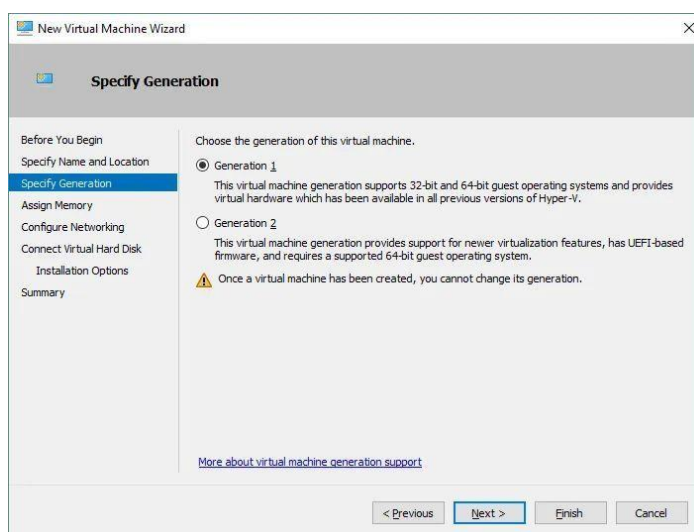

When in Hyper-V Manager, click on the “action” tab, then select “new” > “virtual machine.”

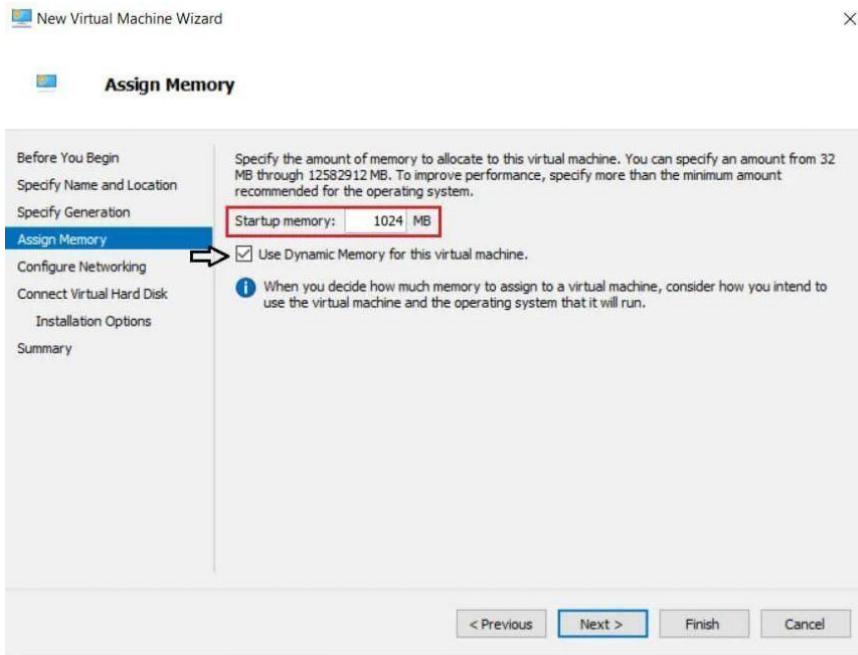

Give a name and tick store if you want select different locations then next

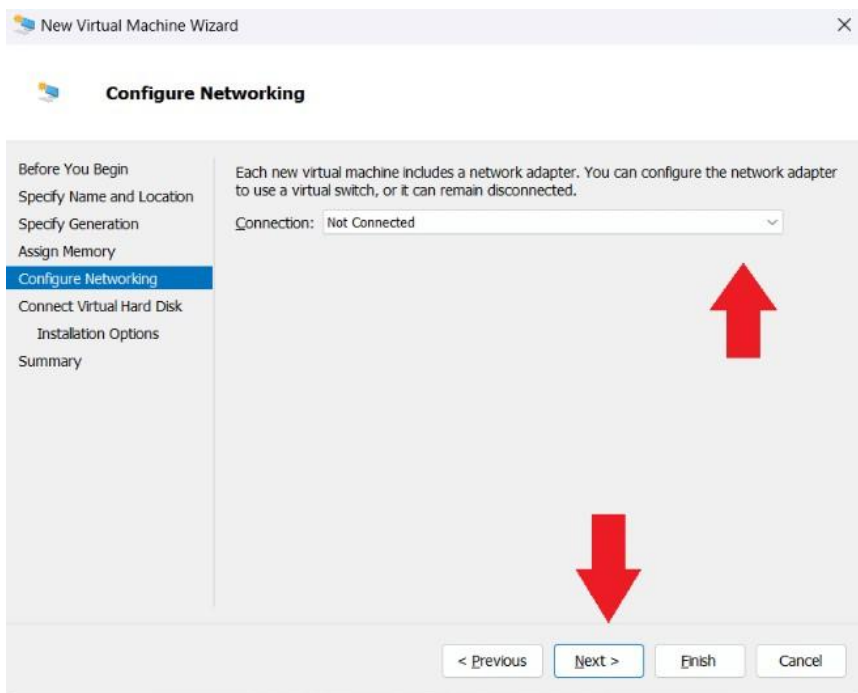

Select which Generation you want then next

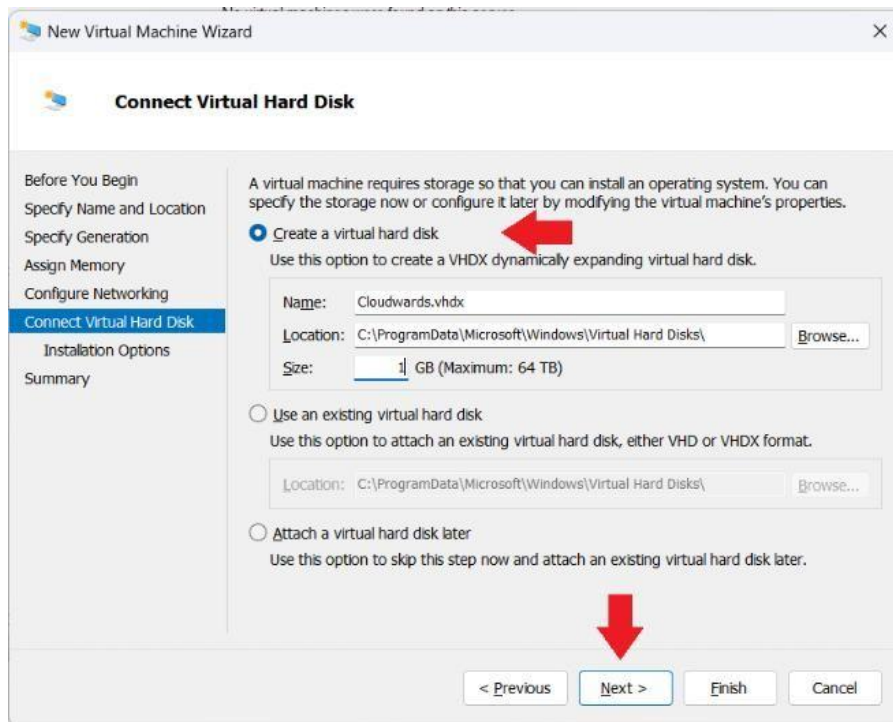

Give some memory and tick use dynamic memory I you are using it for sandbox or inside memory usage

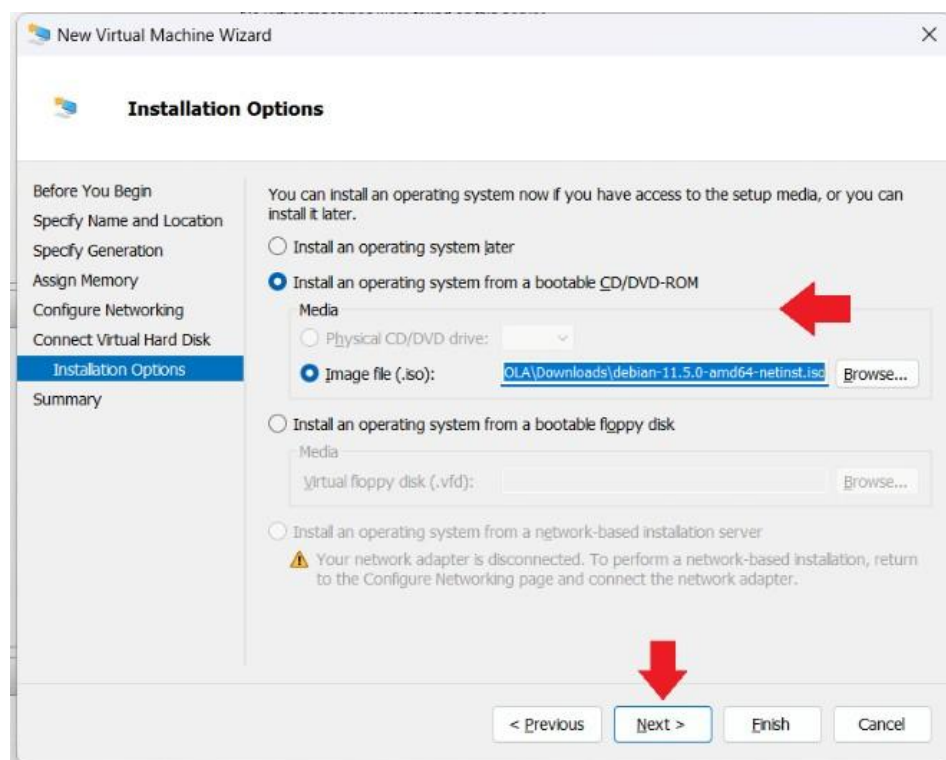

Make sure its connected to the net

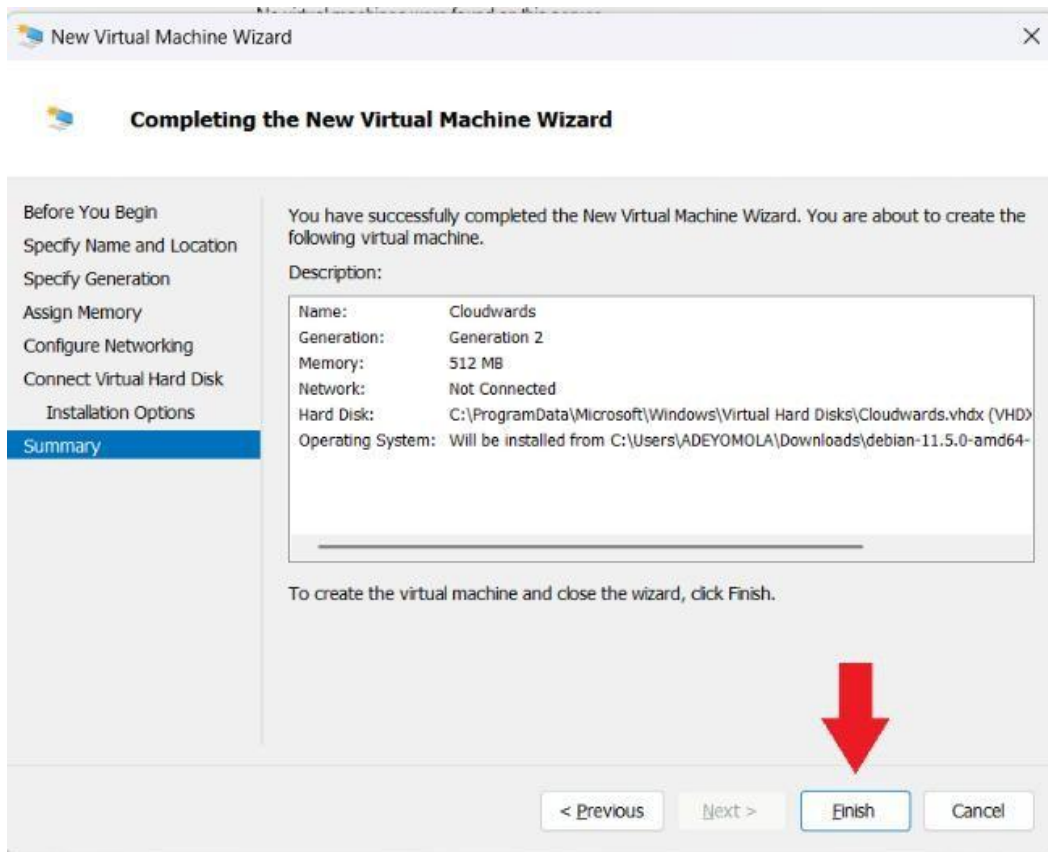

We can create a VHD with like 60GB or use a existing one click next

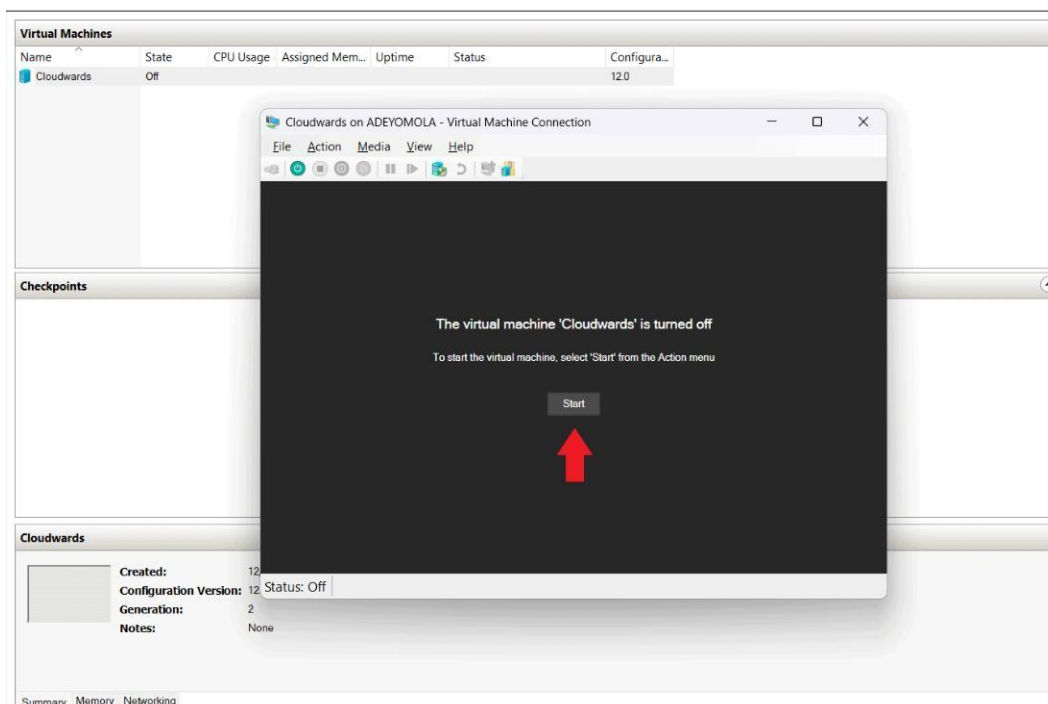

We can select the ISO file from the folder click next

Click on Finish

After that we can start the virtual machine

We can configure the VM settings to make changes in the VM hardware like changing network settings and adding or removing the Hardware
