

Install and configure ADFS and ADRMS in Server -2019-16

Introduction

- **ADFS (Active Directory Federation Services)** provides Single Sign-On (SSO) to users so they can access multiple systems and applications using one set of credentials. It is commonly used to integrate on-premises Active Directory with cloud services like Office 365.
- **ADRMS (Active Directory Rights Management Services)** protects digital information from unauthorized use. It allows administrators to enforce usage policies such as who can open, edit, print, or forward documents and emails.

These services increase security and improve user experience in enterprise environments.

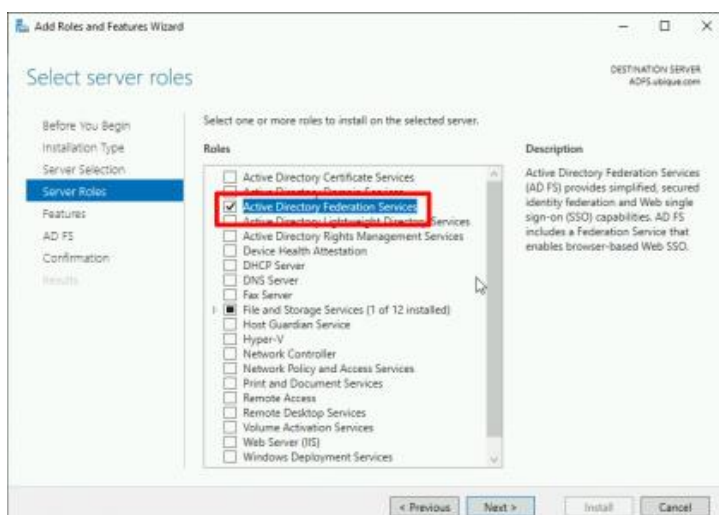

Steps to Install and Configure ADFS

Step 1: Prerequisites

- Active Directory Domain Services must be installed.
- A domain certificate (SSL) must be available for the federation service name (e.g., fs.company.local).

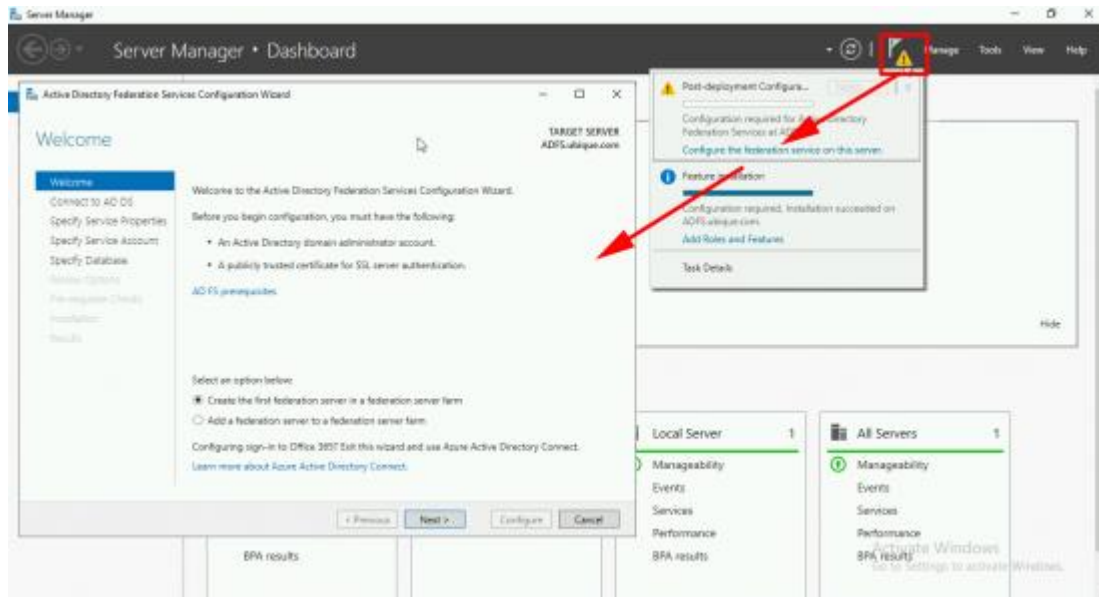

Step 2: Install ADFS Role

1. Open **Server Manager** → **Add Roles and Features**.
2. Select **Active Directory Federation Services** role.
3. Complete installation.

Step 3: Configure ADFS

1. After installation, click **Configure the federation service on this server**.
2. Select **Create the first federation server in a federation server farm**.
3. Provide a domain admin account.
4. Select the SSL certificate and specify federation service display name.
5. Complete the configuration and restart services.

Step 4: Verify ADFS

- Open a browser and go to:
- <https://fs.company.local/adfs/ls/IdpInitiatedSignon.aspx>
- If login succeeds, ADFS is working.

Steps to Install and Configure ADRMS

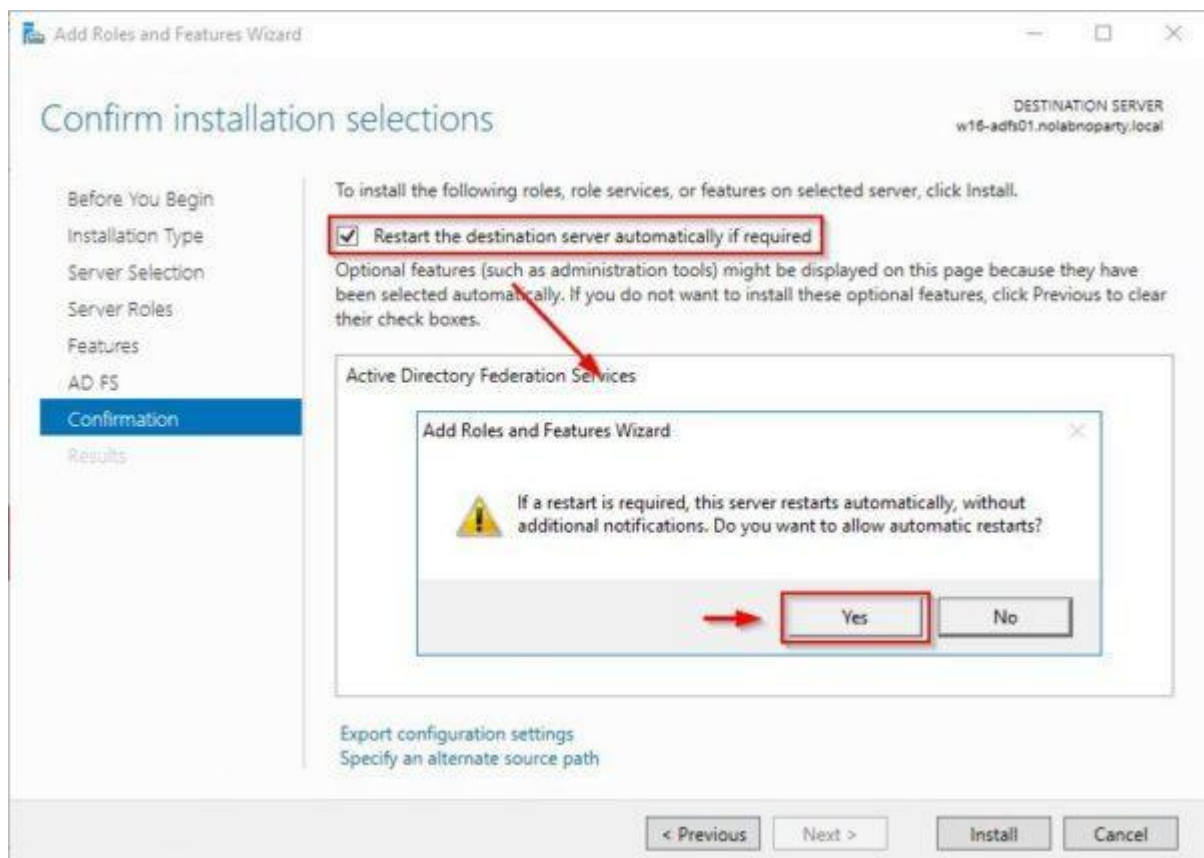

Step 1: Prerequisites

- Server must be joined to the domain.
- SQL Server or Windows Internal Database must be available.
- Service account must be created in AD.

Step 2: Install ADRMS Role

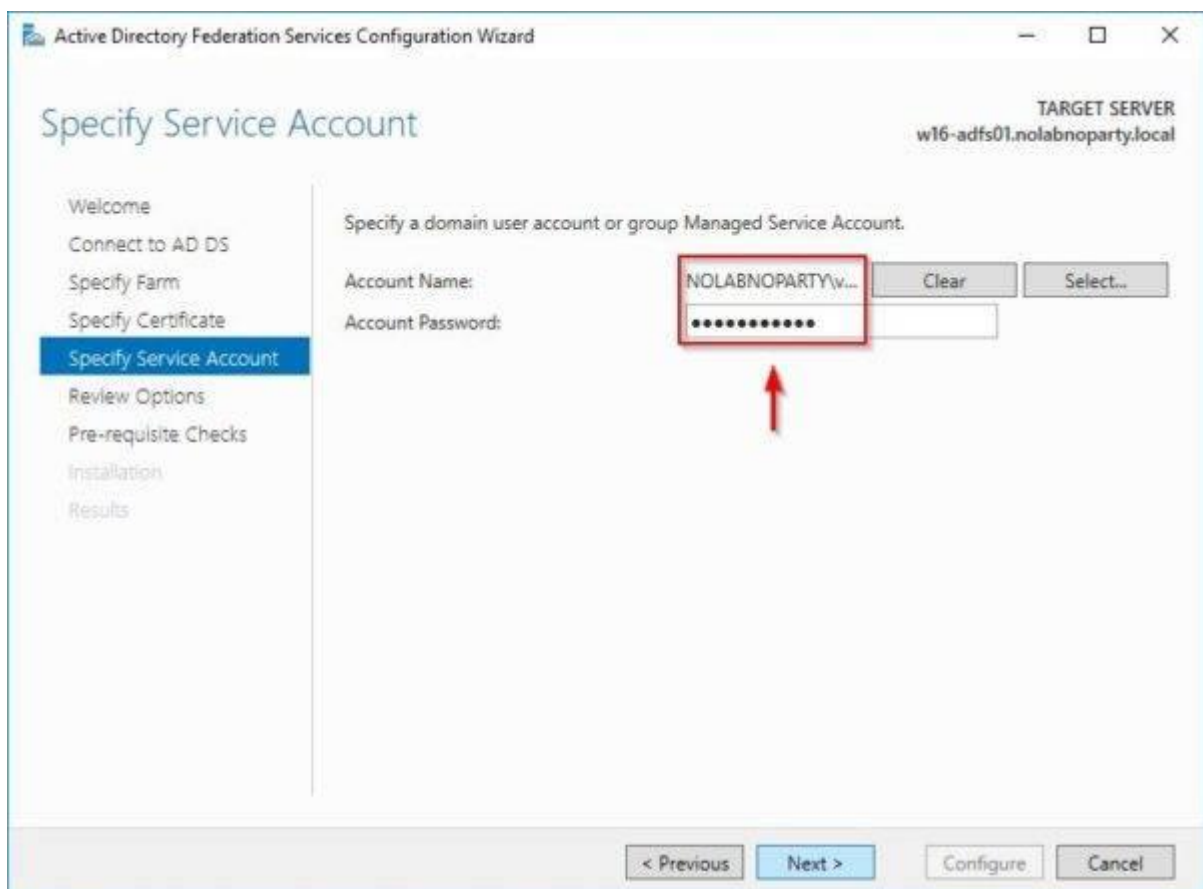

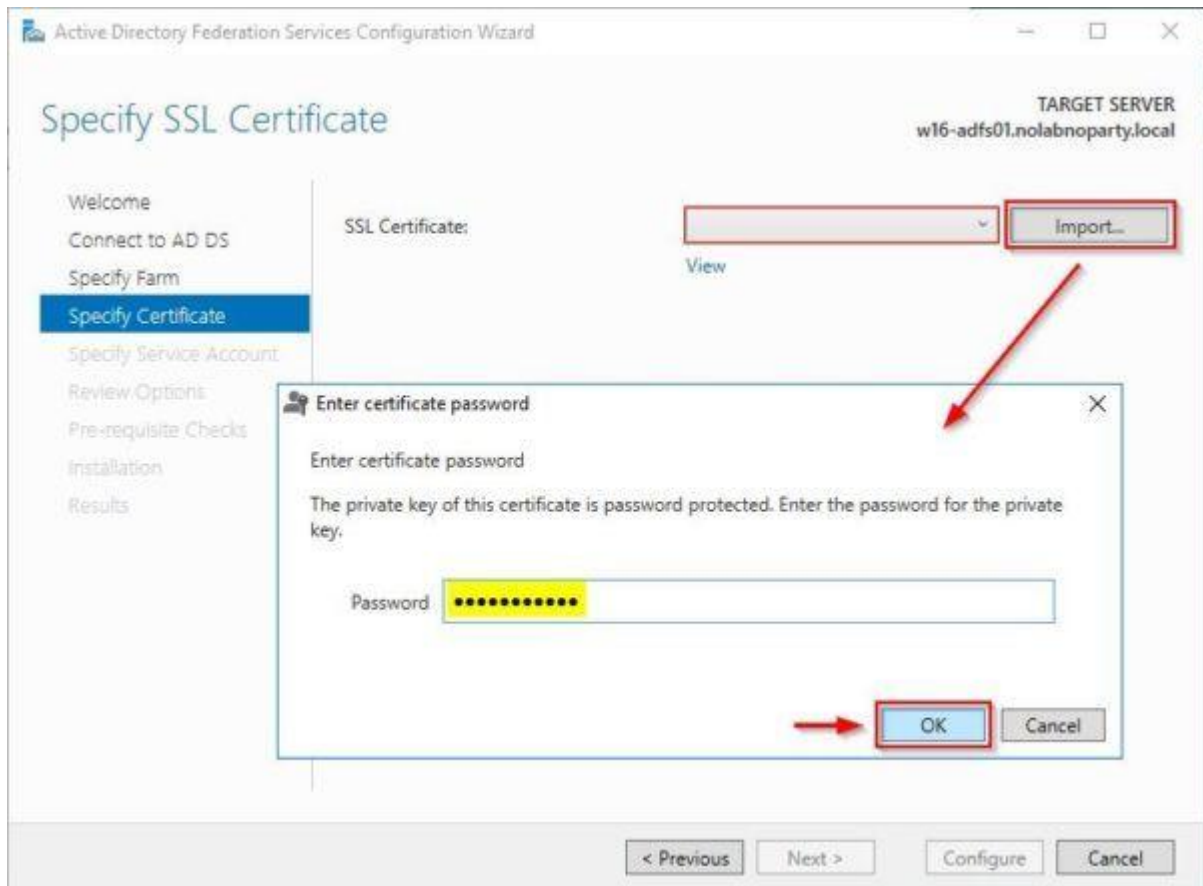

1. Open **Server Manager** → **Add Roles and Features**.
2. Select **Active Directory Rights Management Services**.

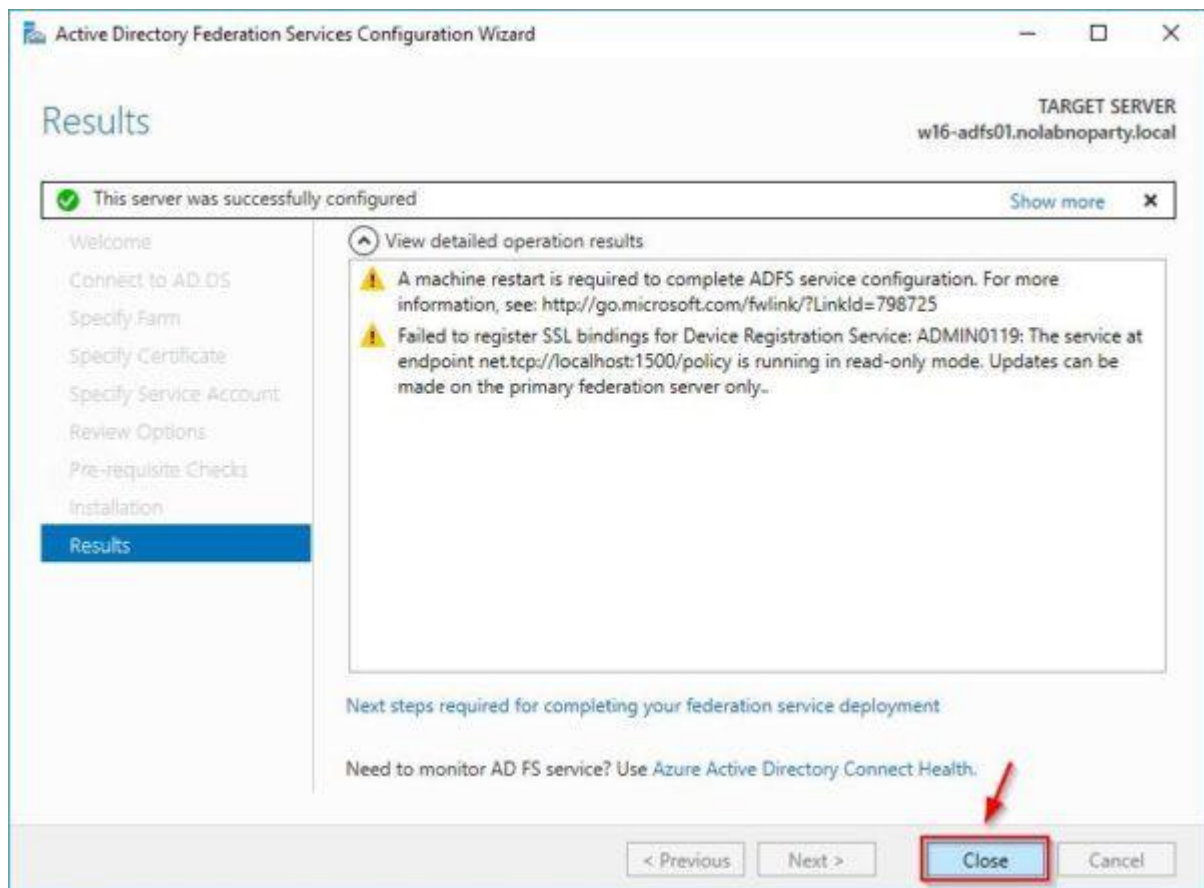

3. Include the **Identity Federation Support** feature if required.
4. Complete installation.

Step 3: Configure ADRMS

1. Open **AD RMS Console** from **Tools**.
2. Right-click the server → **Configure AD RMS on this server**.
3. Create a new **AD RMS root cluster**.
4. Choose the database (SQL or WID).
5. Specify the service account created earlier.
6. Configure the cluster key storage (password protected).
7. Assign the AD RMS Service Connection Point (SCP) to Active Directory.

Step 4: Test ADRMS

- Use a client with Microsoft Office.
- Create a Word document → go to **File → Info → Protect Document → Restrict Access**.
- Apply permissions (e.g., allow only specific users to read).
- Check if access restrictions apply correctly.
